

Estimating road and railway infrastructure capacity and costs

Alex Körner, John Dulac

alexander.koerner@iea.org

Focus on infrastructure

- IEA infrastructure partnerships:
 - UIC (rail)
 - IRF (roads)
 - UITP (public transport)
 - WRI EMBARQ (BRT)
- Structured analysis
 - Travel patterns and infrastructure demand
 - Transport fuel T&D/re-charging infrastructure
- Infrastructure insights (2013)
www.iea.org/publications/freepublications/publication/name,34742,en.html
- ETP 2012 chapter on hydrogen
- Conference paper on EV recharging infrastructure

Travel demand to 2050

Passenger and freight travel by mode in the ETP 4DS

Total travel demand increased by almost 50% in the last decade and is likely to double until 2050 compared to 2010 levels.

With no dedicated policies, road travel might almost double as well.

Most of the demand growth is coming from non-OECD countries.

Historic infrastructure trends

Road (paved lane-km)

Rail (track-km)

Sources: IEA analysis based on IRF (2012) and UIC (2012)

Global road additions continue to grow at a rapid pace, while rail capacity has remained stagnant or even decreased.

Approx. 2% global GDP is spent on road and rail infrastructure!

Required road capacity to 2050

Paved road lane-km in the ETP 4DS

Global roads are likely to grow by nearly 25 million paved lane-km by 2050 in the 4DS, demanding for almost 80 trillion USD cumulative investment (110 trillion USD incl. parking space).

Benefits of avoided/shifted travel

Avoid/shift approach (2DS) versus business as usual (4DS)

Road

Rail

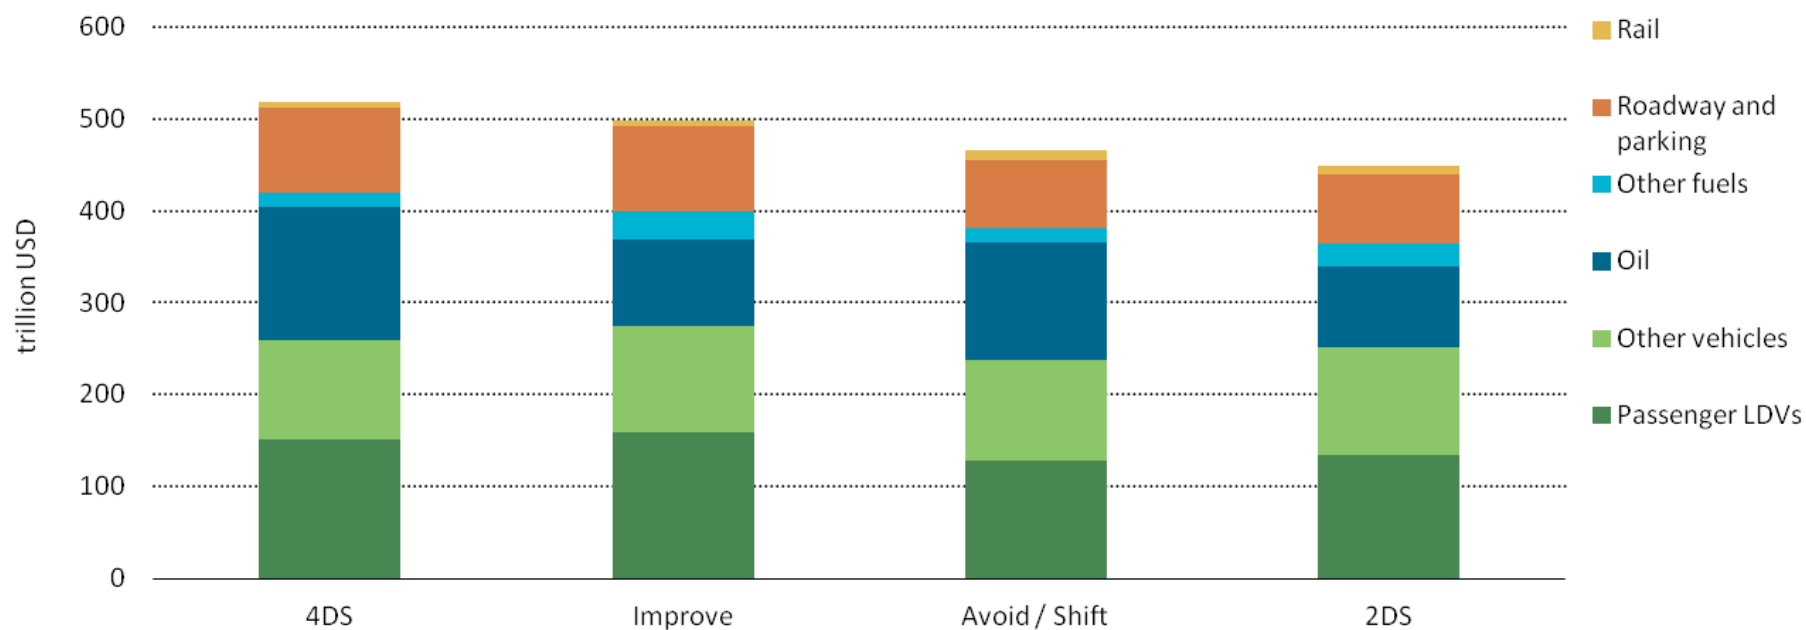

An 'avoid/shift' approach could reduce road additions to 2050 by nearly 11 million paved lane-km. Rail would need to increase by 200 000 track-km

Potential cumulative savings due to less road infrastructure: USD 20 trillion

Additional 115 000 km new HSR ~ USD 4 trillion

ETP 2012 scenarios: Cost comparison

The IEA *Improve* case (focus on technology) reduces expenditures on fuels, whereas the *Avoid/Shift* case (focus on behavioural change) cuts down infrastructure and vehicle costs.

An 'avoid, shift and improve' (2DS) approach could save as much as USD 90 trillion over 4DS spending. More than 20% of these cumulative savings can come from less infrastructure expenditures.

Example: Road IS projection

- Based on historic road occupancy levels: Region specific ratio of vehicle-pkm per lane-km
- Future infrastructure expansion with respect to:
 - Construction capacity limit: How fast has road infrastructure been added in the past (e.g. China on average 350,000km per year)?
 - Density limits: Ratio of lane-km per land area; currently Japanese density is taken as constraint
 - Road occupancy limit: What is the acceptable road occupancy limit (currently: 1.8 mio vkm per lane km; for comparison: OECD average 0.5 mio vkm per lane km)

IEA road/rail infrastructure DB

- Infrastructure data from IRF, UIC, ITDP, EMBARQ
- Cost data: More than 1300 individual projects in 110 countries from ITF, IRF, UIC, ADB and regional initiatives
- Data issues:
 - Limited data on infrastructure on a detailed level (*e.g. number of lanes, % paved, annual updates*)
 - Even less data on infrastructure investments (*e.g. project costs, how money is spent, impact of investments*)

Data are key to understanding progress, future infrastructure needs and long-term impacts of investment decisions!

OECD

Conclusions

- Road infrastructure accounts for almost 20% of all cumulative transport expenditures 2010 to 2050 – Need to re-think that!!!
- Infrastructure costs can be a key piece in climate change mitigation scenarios
- Avoid /Shift: Rail and public transit (bus, metro, light rail, BRT) offer big potential to accommodate travel growth at lower long-term costs while reducing GHG emissions at the same time
- Emerging/developing countries are primary targets, as the transport system is largely to be built
- Infrastructure data is imperative to understand how projected travel growth can be accommodated, and what are potential effects on congestion levels/utilization rates

A close-up photograph of several dandelion seed heads against a bright, white background. The seeds are delicate and wispy, with some showing a reddish-brown hue. The stems are dark and thin.

Thanks!

Data needs

- Data requirements to provide better understanding:
 - Extent and class of infrastructure (length, capacity, paved vs. unpaved)
 - Age structure (e.g. state of repair)
 - Good estimates of specific cost of infrastructure (e.g. per km: capital, reconstruction, O&M)
 - Urbanization rates, density
 - Classification of land profile
 - Identification of main transport axis
 - Time series/detailed infrastructure investment data

Data value

- Infrastructure data is imperative to understand how projected travel growth can be accommodated, and what are potential effects on congestion levels and utilization rates
- Financing infrastructure and macro-economic decision taking:
 - Road investments typically are less expensive (short term) but have higher long-term operational and maintenance costs
 - Rail and public transit (metro, light rail, BRT) offer significant potential to accommodate travel growth at lower long-term costs (while reducing energy consumption and emissions)
- Providing a complete picture on energy use, emissions and costs of the transport sector
 - Infrastructure costs can be a key piece in climate change mitigation scenarios

Global historic trends - investment

Average global spending on road and rail infrastructure

Sources: IEA analysis based on ITF and ADB member country data

Global road expenditures on capital construction have continued to increase in recent years, accounting for more than 50% of total spending.

Approx. 2% global GDP is spent on road and rail infrastructure!

Capacity: Rail vs. road

Whilst road infrastructure carrying capacity (tkm/pkm per km) stayed almost constant, rail capacity increased by 50% over the last decade.

In absolute terms rail capacity is about 12 times the capacity of road transport

Role of investments to achieve 2DS

Shifts in investments to bus and rail infrastructure are cost effective compared to present spending

10-fold increase in BRT: ~USD 400 billion (0.5% road investments in 4DS)

115 000 km new HSR: ~USD 4 trillion (5% road investments in 4DS)
